FOREWORD

This report was prepared for the Applied Mathematics Research Laboratory, Aerospace Research Laboratories by Dr. H. Leon Harter, under Task 7071-01, Research in Mathematical Statistics and Probability, of Project 7071, Mathematical Techniques of Aeromechanics. It is a sequel to the author's book, New Tables of the Incomplete Gamma-Function Ratio and of Percentage Points of the Chi-Square and Beta Distributions, which was recently published through the Government Printing Office.

Acknowledgment is made to Mr. William H. Sammons, who suggested to the author the need for tables for additional values of the parameters.

The author wishes to thank Mr. Eugene H. Guthrie for assistance in reproducing the tables on the IBM 407 tabulator and Miss Eva Brandenburg for typing the manuscript.

ABSTRACT

The following tables, together with brief discussions of methods of computation and uses, are included:

(1) a nine-decimal-place table of the incomplete Gamma-function ratio, $I(u, p)$, for $p = .95(.05)4$ and u at intervals of 0.1; and (2) a six-significant-figure table of the percentage points, corresponding to cumulative probabilities $P = .0001, .0005, .001, .005, .01, .025, .05, .1(.1).9, .95, .975, .99, .995, .999, .9995$, and .9999, of the chi-square distribution with $v = 0.1(0.1)10$ degrees of freedom. Both tables are accurate to within a unit in the last place.

I. Introduction

The mathematical formulations underlying the tables included in this report have been given in previous publications by the author [1], [2], and will not be repeated here. The methods of computation differ only in minor respects from those discussed in detail in [1] and [2], and hence it is necessary here only to summarize the methods and point out the differences. Some, but not all, of the uses of the tables discussed in [1] are such that only integral values of the parameters are of interest. Examples will be given of uses of the tables for non-integral parameter values.

2. Methods of Computation

2.1. The Incomplete Gamma-Function Ratio. The incomplete Gamma-function ratio, $I(u, p)$, is given by

$$(1) \quad I(u, p) = \frac{1}{\Gamma(p+1)} \int_0^{u\sqrt{p+1}} v^p e^{-v} dv.$$

The area corresponding to the integral on the right-hand side of Equation (1) was divided into strips by vertical lines erected at intervals of 0.1 in u , and the area of each strip except the first was found by numerical integration by use of a seven-point formula, with repeated halving of the interval until successive results, after the indicated division by $\Gamma(p+1)$, differed by no more than 10^{-13} . Numerical integration could not be used to determine the area of the first strip, which was computed by expanding e^{-v} [in the integrand on the right-hand side of Equation (1)] in series, integrating term by term, evaluating between the limits 0 and $0.1\sqrt{p+1}$, and performing the indicated division by $\Gamma(p+1)$. For a given value of p , the value of $I(u, p)$ for $u = 0.1 k$ (k a non-negative integer) is the sum of the areas of the first k strips. Since $k < 10^3$ for all values given in the table, the truncation error is certainly less than 10^{-10} . The computations were performed in double precision on the IBM 7094 computer with FORTRAN programming, and the results were rounded to nine decimal places and punched on IBM cards. This gives rise to a rounding error not exceeding 5×10^{-10} . Since the sum of the truncation error and the rounding error is less than 10^{-9} , the results are accurate to within a

unit in the ninth decimal place. The results are shown in Table 1, which was reproduced from a table printed from the cards by use of the IBM 407 tabulator. Since the tabulator does not have lower-case letters, $I(u, p)$ was printed as $I(U, P)$.

2.2. Percentage Points of the Chi-Square Distribution. The author [1], [2] has discussed three methods of computing percentage points of the chi-square distribution. These may be summarized as follows: (1) interpolating inversely in Table 1 to find the percentage points of u for $p = v/2 - 1$, then multiplying by $\sqrt{2v}$; (2) subtabulating in the table of $\log I'(u, p)$, where $I'(u, p) = I(u, p) / u^{p+1}$, given by Karl Pearson [4], then taking antilogarithms and multiplying by u^{p+1} , and finally interpolating inversely and multiplying by $\sqrt{2v}$; and (3) iterating on the basis of a series expansion suggested by Pearson and Hartley [3], obtaining successively $\chi_0^2 = 2 \{ P \Gamma(v/2 + 1) \}^{2/v}$, $\chi_1^2 = \chi_0^2 \{ 1 - [v/(v+2)] \chi_0^2/2 \}^{-2/v}, \dots, \chi_k^2 = \chi_{k-1}^2 \{ 1 - [v/(v+2)] \chi_{k-1}^2/2 \cdot 1! + \dots + (-1)^k [v/(v+2k)] (\chi_{k-1}^2)^k / 2^k \cdot k! + \dots \}^{-2/v}, \dots$. Method 1 attains its greatest accuracy for large values of P (cumulative probability) and v (degrees of freedom); method 3, for small values of P and v ; and method 2, for intermediate values of P and v . Since the sets of values of P and v for which methods 1 and 3 provide results which are accurate to within a unit in the sixth significant figure leave no gaps, but actually overlap, method 2 is not really needed, but results obtained by this method serve as a check on

those obtained by the other methods. All of the computations were performed on the IBM 7094 computer with FORTRAN programming. Single precision was adequate for method 2; for methods 1 and 3 double precision was used. The results were punched on IBM cards, and Table 2 was reproduced from a table printed from the cards by use of the IBM 407 tabulator. The values given in Table 2 are those obtained by method 1, with the following exceptions, which were obtained by method 3: (1) $\nu = 0.1(0.1)0.5$, $P \leq .9$; (2) $\nu = 0.6(0.1)1.0$, $P \leq .8$; (3) $\nu = 1.1(0.1)1.5$, $P \leq .6$; (4) $\nu = 1.6(0.1)2.5$, $P \leq .3$; (5) $\nu = 2.6(0.1)3.5$, $P \leq .2$; (6) $\nu = 3.6(0.1)4.0$, $P \leq .1$; (7) $\nu = 4.1(0.1)5.0$, $P \leq .05$; (8) $\nu = 5.1(0.5)5.5$, $P \leq .025$; (9) $\nu = 5.6(0.1)6.5$, $P \leq .01$; (10) $\nu = 6.6(0.1)7.0$, $P \leq .005$; (11) $\nu = 7.1(0.1)9.0$, $P \leq .001$; and (12) $\nu = 9.1(0.1)10.0$, $P \leq .0005$. The tabular values are printed in E-format, in which the number following the E is the power of 10 by which the number preceding the E must be multiplied.

2.3. Checks on Accuracy of Tables. In addition to the internal checks already mentioned, both tables were differenced on the IBM 7094 computer to ascertain that no gross errors have been introduced and to verify that the results are accurate to within a unit in the last place as stated. Input to the difference programs was from the cards used to print the tables on the IBM 407 tabulator.

3. Uses of Tables

3.1. The Incomplete Gamma-Function Ratio. The author [1] has given

examples of uses of tables of the incomplete Gamma-function ratio based on its relation to the cumulative probabilities of the Pearson Type III and Poisson distributions. Only the former is of interest here, since the latter is a discrete distribution, the number of occurrences of an event being an integer, so that the tables of $I(u, p)$ for integral values of p given in [1] are all that is required.

Let the random variable t have a Pearson Type III distribution with mean $\mu = 0$, variance $\sigma^2 = 1$, and skewness a_3 . The following relation holds:

$$(2) \quad \Pr[t \leq x] = I(2a_3^{-1} + x, 4a_3^{-2} - 1).$$

If $a_3^2 > 0.8$, so that $4a_3^{-2} - 1 < 4$, Table 1 is useful in evaluating the probability given by Equation (2). It is especially useful for $|a_3| > 1.1$, which is the largest value included in the tables computed by Salvosa [5]. Single or double interpolation will be required unless $u = 2a_3^{-1} + x$ is a multiple of 0.1 and/or $p = 4a_3^{-2} - 1$ is a multiple of 0.05. If interpolation in p is required, it can be performed much more accurately than in Table 1 of [1], where the interval is ten times as large.

Example 3.1.1. Let t be a random variable having a Pearson Type III distribution with mean $\mu = 0$, variance $\sigma^2 = 1$, and skewness $a_3 = 2.5$. Find the probability that $t \leq 1$. --From Equation (2) and Table 1 we find

$$\Pr[t \leq 1] = I(1.8, -.36) = .873750665,$$

the results of 7-point and 8-point Lagrangian interpolation agreeing to 9 decimal places.

3.2. Percentage Points of the Chi-Square Distribution. The author [1] has enumerated four populations for which ratios of specified functions of sample estimators and population parameters have chi-square distributions. A table of percentage points of the chi-square distribution is needed in testing hypotheses about and setting confidence bounds on these parameters. For three of the four populations mentioned (normal, exponential, and Weibull), the table of percentage points for integral values of v (degrees of freedom) given in [1] will suffice. For the Gamma population, however, a table of percentage points for non-integral values of v , such as Table 2 of the present report, will be useful. For the Gamma population with location parameter θ_0 , scale parameter θ , and shape parameter a , the ratio $2na\bar{\theta}/\theta$, where $\bar{\theta}$ is an unbiased estimator of θ based on a sample of size n and is defined by $\bar{\theta} = \sum_{i=1}^n x_i/n$, has a χ^2 distribution with $2na$ degrees of freedom. When $2na \leq 10$, Table 2 can be used to find the percentage points required in testing and estimation. If $2na$ is not a multiple of 0.1, interpolation will be necessary, but it can be performed much more accurately in Table 2 of this report than in Table 2 of [1], where the interval in v is ten times as large.

Example 3.2.1. For a sample of size 6 from a Gamma population with shape parameter $a = 0.8$, the unbiased estimator $\bar{\theta}$ of the scale parameter θ , as defined above, is 92.5. Determine a 99% upper confidence bound on θ . The required bound is given by $9.6 \bar{\theta}/\chi^2_{.01, 9.6} = 9.6(92.5)/1.144 = 776$.
